Chapter 3

System Buses

Program Concept

- Hardwired systems are inflexible
- General purpose hardware can do different tasks, given correct control signals
- Instead of re-wiring, supply a new set of control signals

What is a program?

- A sequence of steps
- For each step, an arithmetic or logical operation is done
- For each operation, a different set of control signals is needed

Function of Control Unit

- For each operation a unique code is provided
 - e.g. ADD, MOVE
- A hardware segment accepts the code and issues the control signals
- We have a computer!

Components

- The Control Unit and the Arithmetic and Logic Unit constitute the Central Processing Unit
- Data and instructions need to get into the system and results out
 - Input/output
- Temporary storage of code and results is needed
 - Main memory

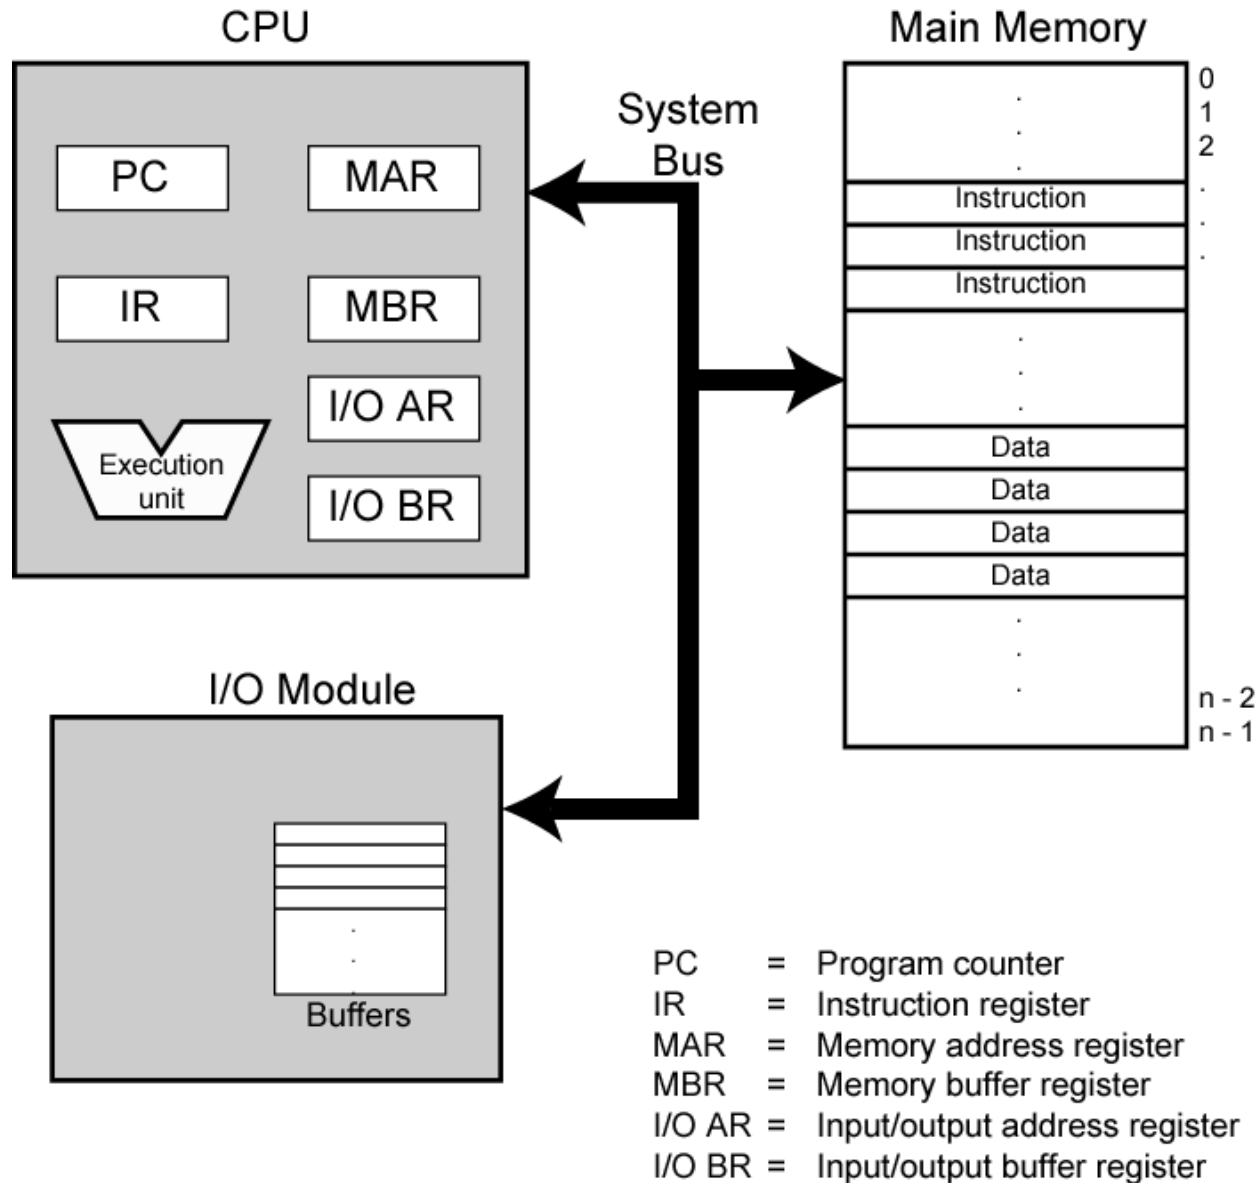

(a) Programming in hardware

(b) Programming in software

Computer Components: Top Level View

Instruction Cycle

- Two steps:
 - Fetch
 - Execute

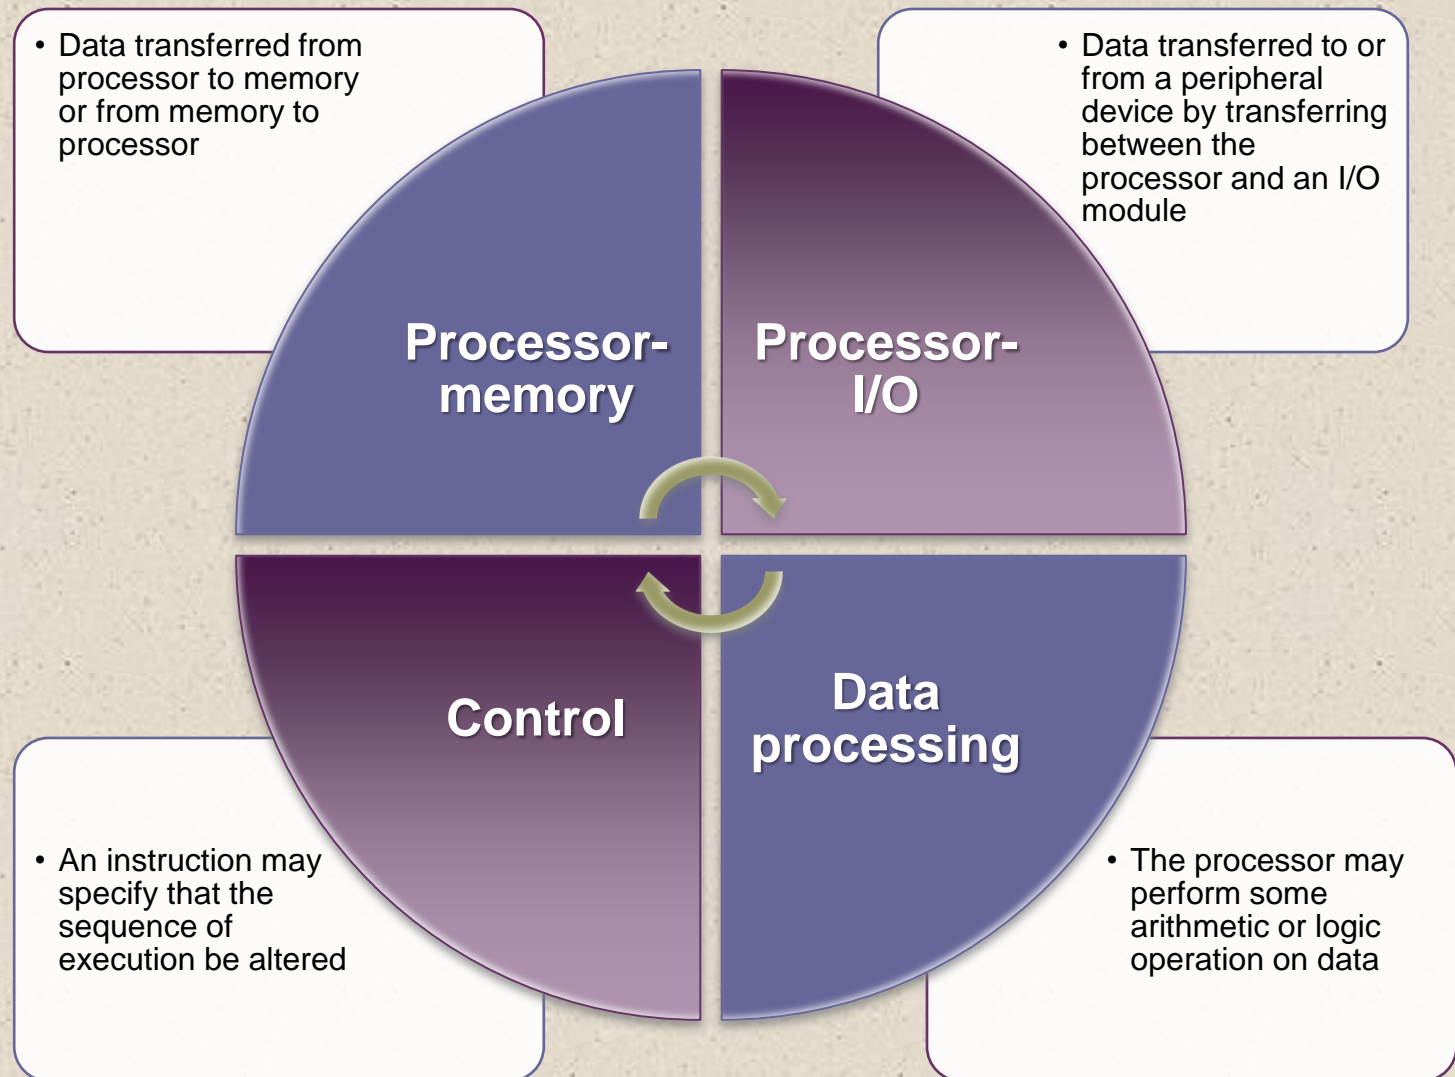

Fetch Cycle

- Program Counter (PC) holds address of next instruction to fetch
- Processor fetches instruction from memory location pointed to by PC
- Increment PC
 - Unless told otherwise
- Instruction loaded into Instruction Register (IR)
- Processor interprets instruction and performs required actions

Execute Cycle

- Processor-memory
 - data transfer between CPU and main memory
- Processor I/O
 - Data transfer between CPU and I/O module
- Data processing
 - Some arithmetic or logical operation on data
- Control
 - Alteration of sequence of operations
 - e.g. jump
- Combination of above

Action Categories

(a) Instruction format

(b) Integer format

Program Counter (PC) = Address of instruction
 Instruction Register (IR) = Instruction being executed
 Accumulator (AC) = Temporary storage

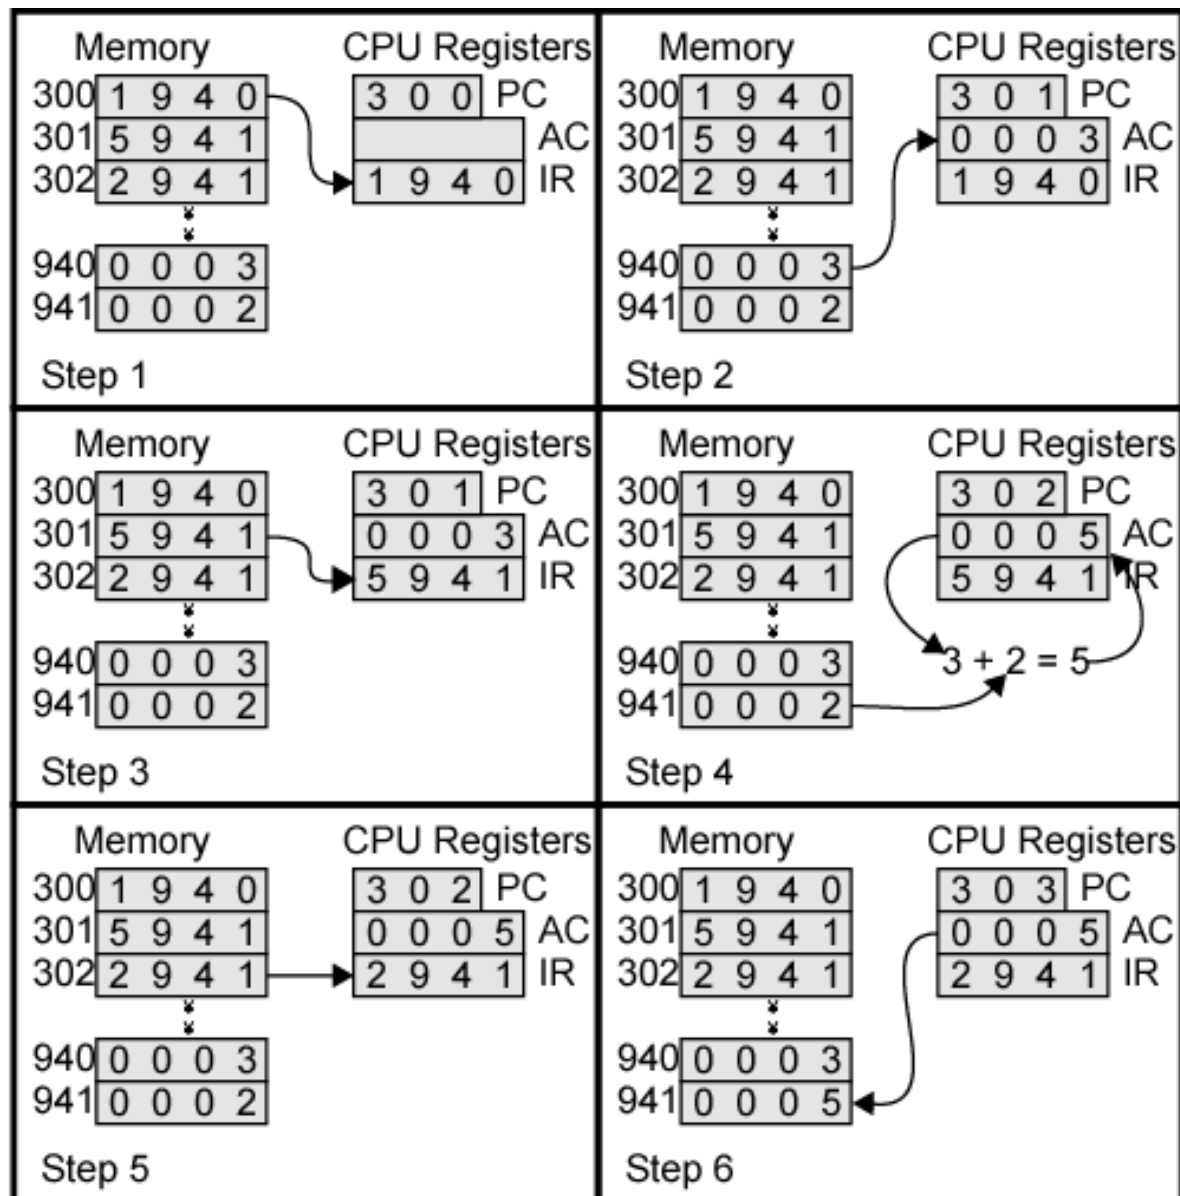

(c) Internal CPU registers

0001 = Load AC from Memory
 0010 = Store AC to Memory
 0101 = Add to AC from Memory

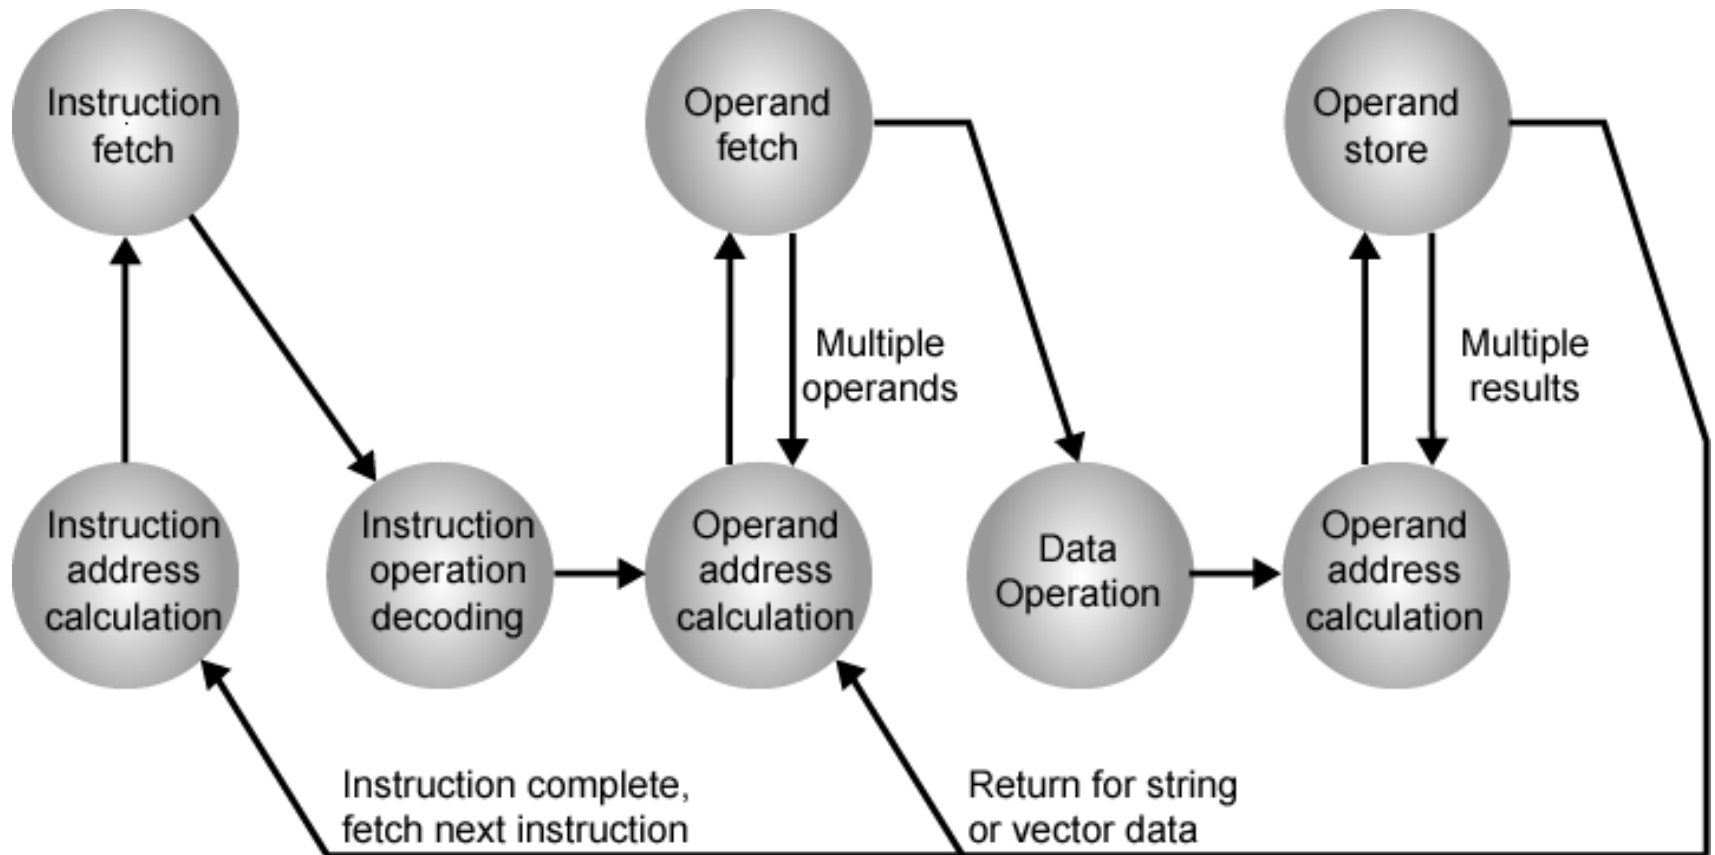

(d) Partial list of opcodes

Figure 3.4 Characteristics of a Hypothetical Machine

Example of Program Execution

Instruction Cycle State Diagram

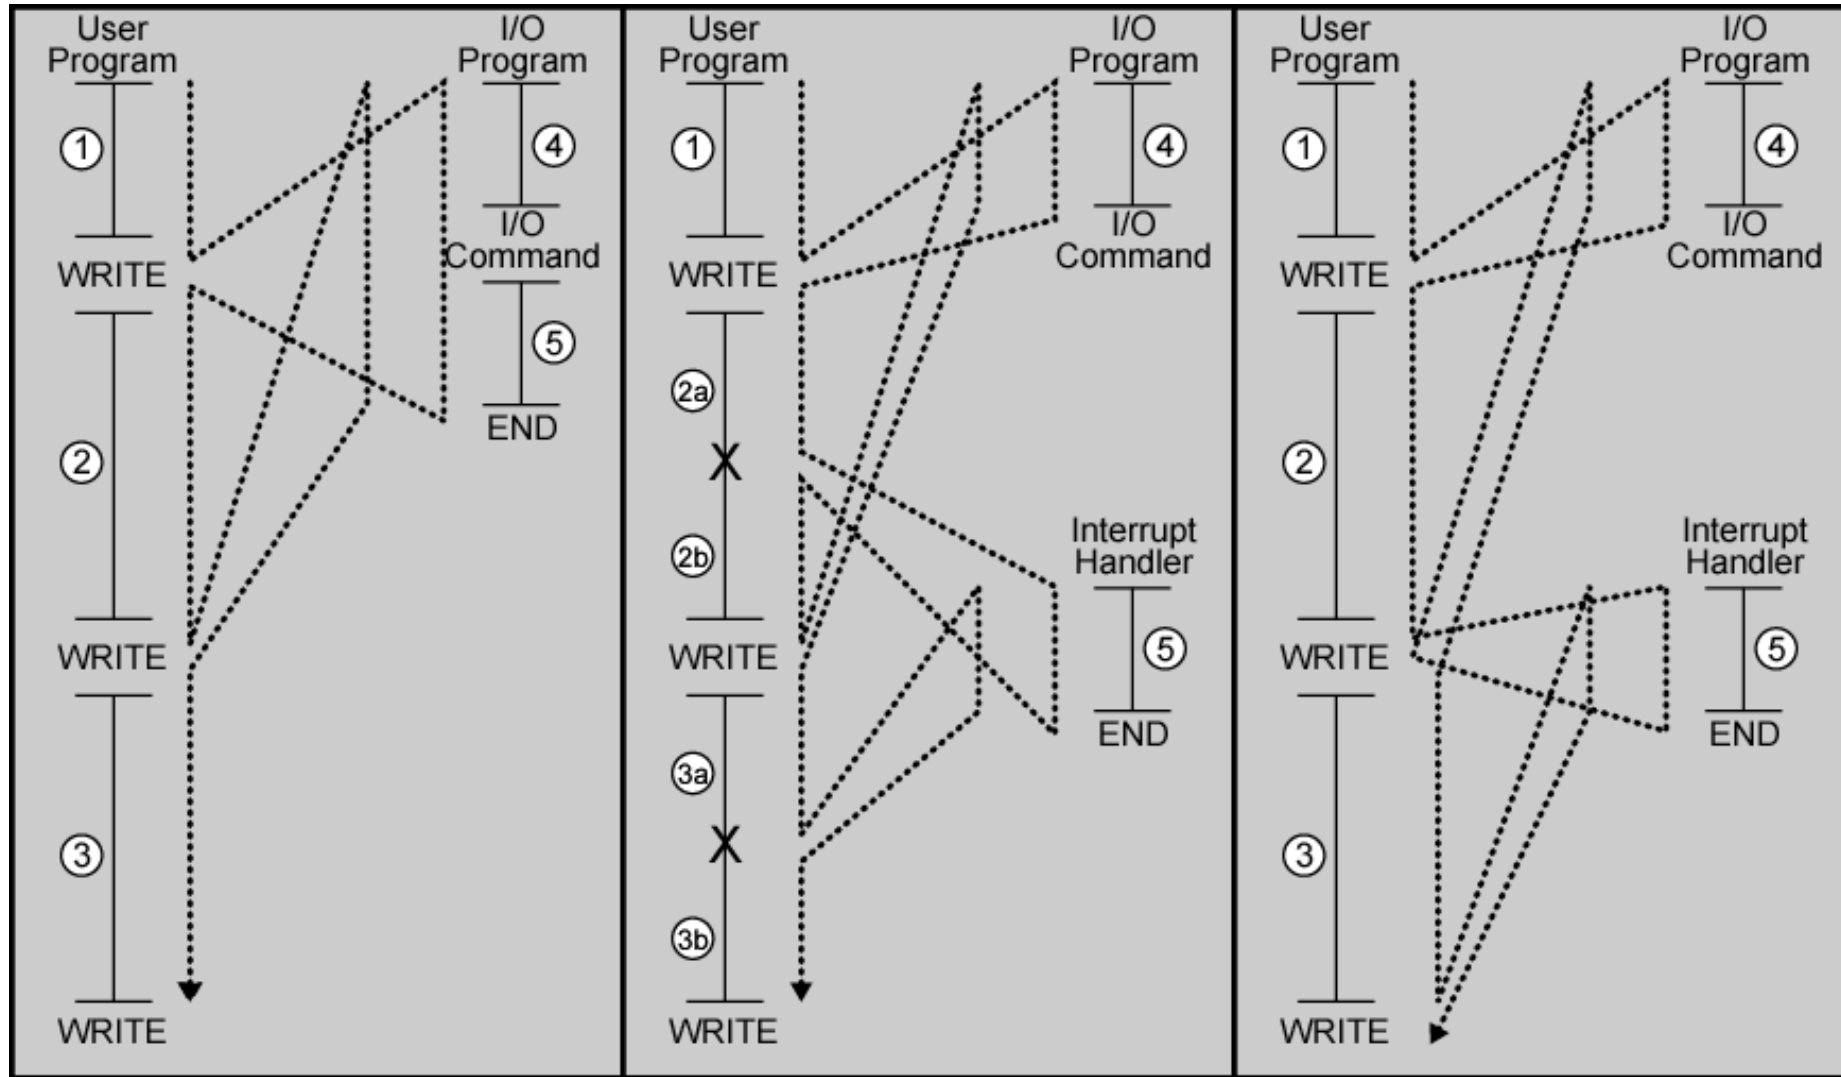

Classes of Interrupts

Program	Generated by some condition that occurs as a result of an instruction execution, such as arithmetic overflow, division by zero, attempt to execute an illegal machine instruction, or reference outside a user's allowed memory space.
Timer	Generated by a timer within the processor. This allows the operating system to perform certain functions on a regular basis.
I/O	Generated by an I/O controller, to signal normal completion of an operation, request service from the processor, or to signal a variety of error conditions.
Hardware failure	Generated by a failure such as power failure or memory parity error.

Interrupts

- Mechanism by which other modules (e.g. I/O) may interrupt normal sequence of processing
- Program
 - e.g. overflow, division by zero
- Timer
 - Generated by internal processor timer
 - Used in pre-emptive multi-tasking
- I/O
 - from I/O controller
- Hardware failure
 - e.g. memory parity error

Program Flow Control

(a) No interrupts

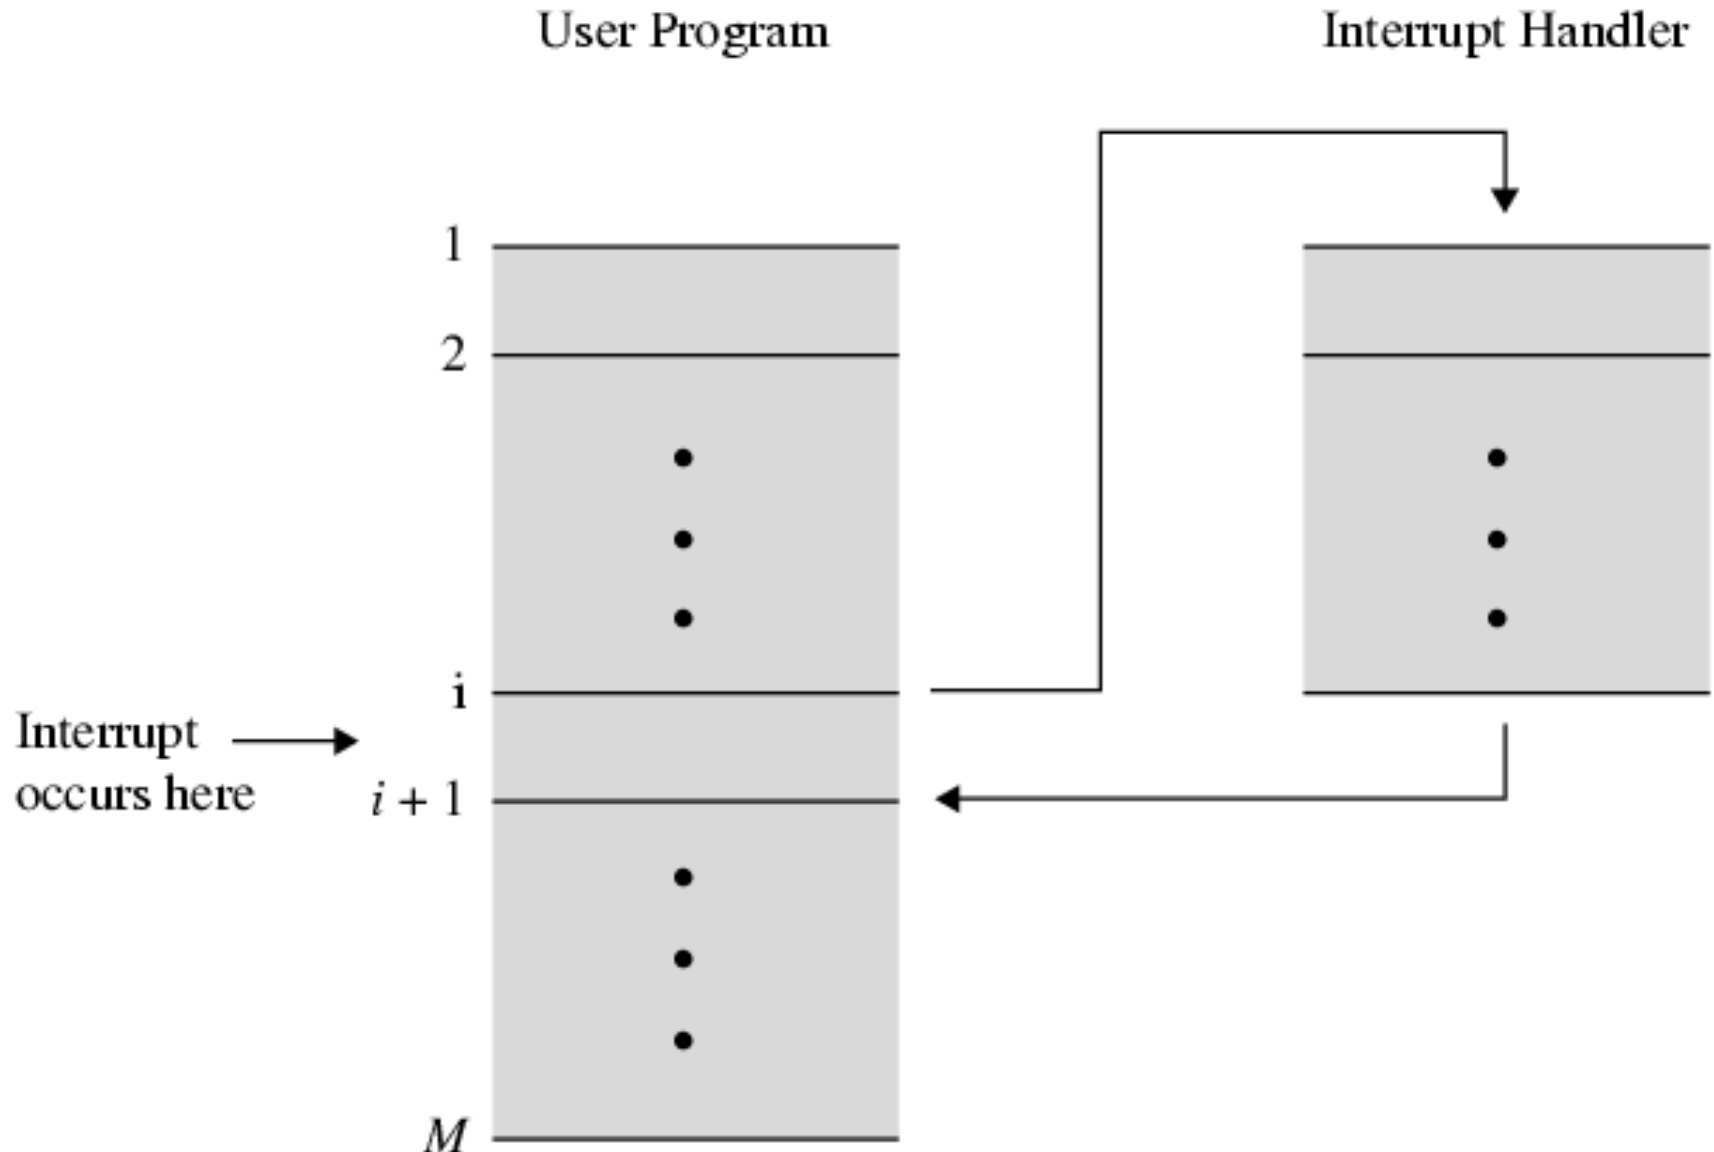

(b) Interrupts; short I/O wait

(c) Interrupts; long I/O wait

Interrupt Cycle

- Added to instruction cycle
- Processor checks for interrupt
 - Indicated by an interrupt signal
- If no interrupt, fetch next instruction
- If interrupt pending:
 - Suspend execution of current program
 - Save context
 - Set PC to start address of interrupt handler routine
 - Process interrupt
 - Restore context and continue interrupted program

Transfer of Control via Interrupts

Instruction Cycle with Interrupts

Program Timing

Short I/O Wait

(a) Without interrupts

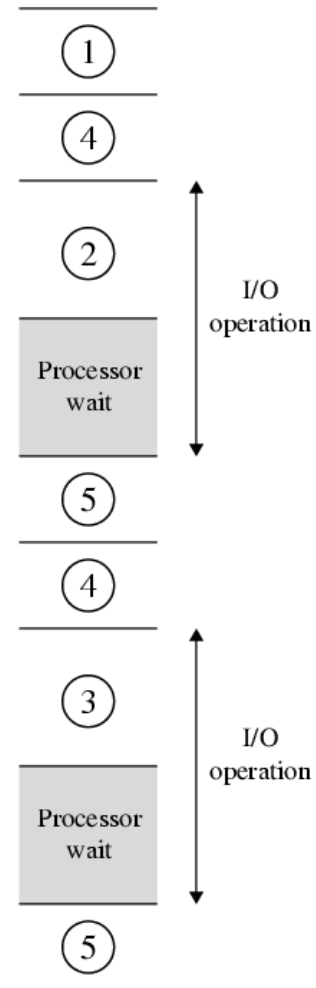

(b) With interrupts

Program Timing

Long I/O Wait

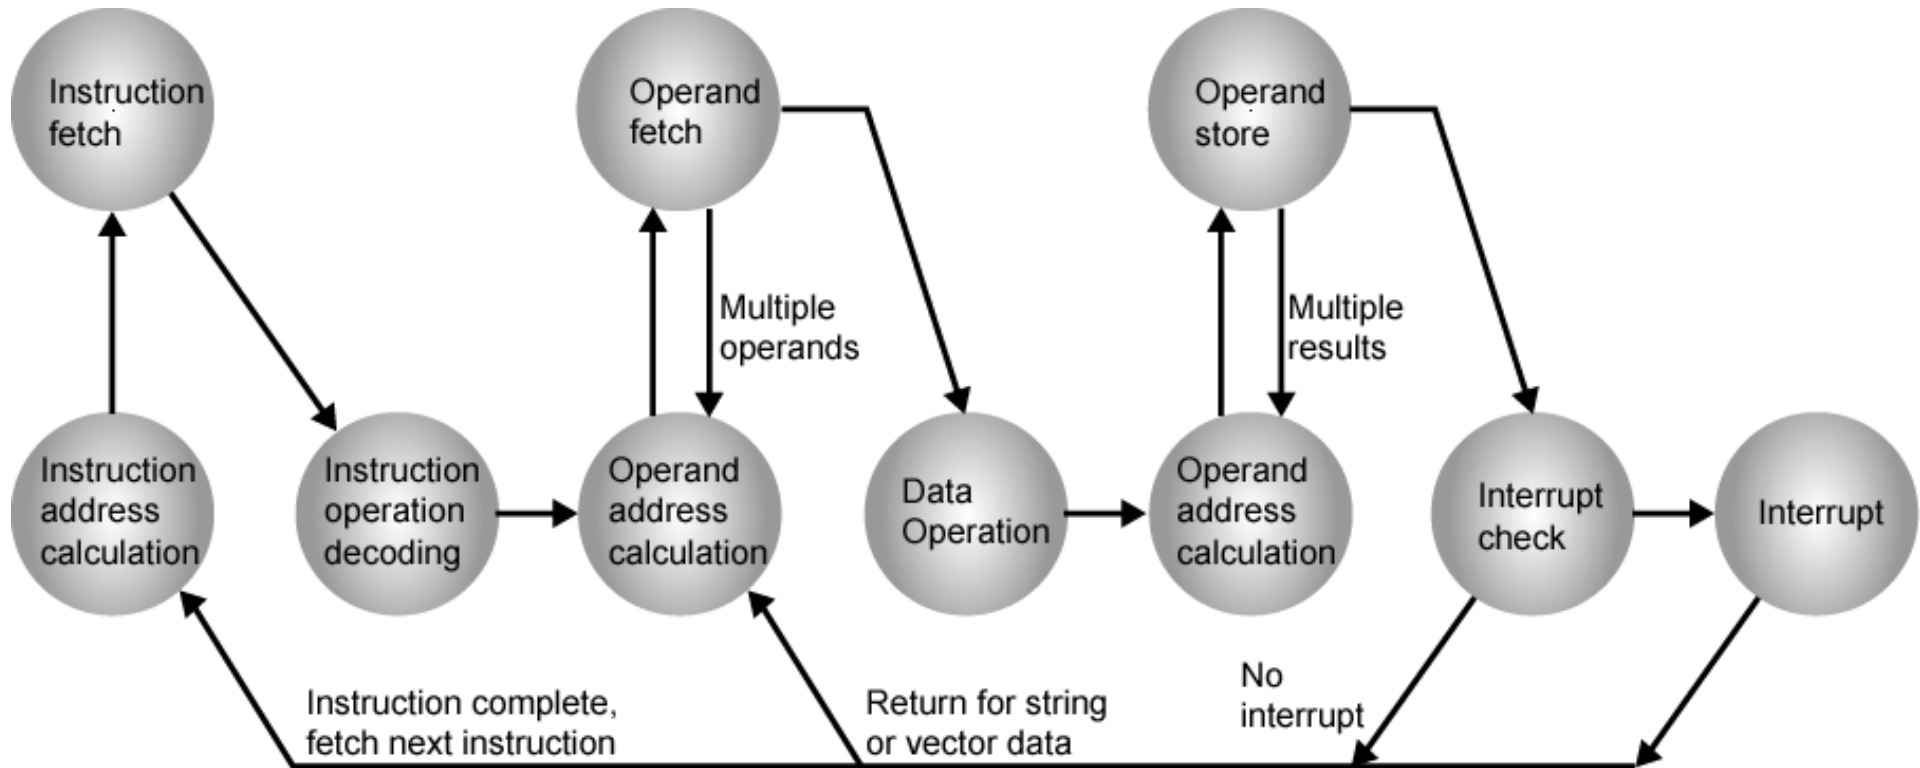

(a) Without interrupts

(b) With interrupts

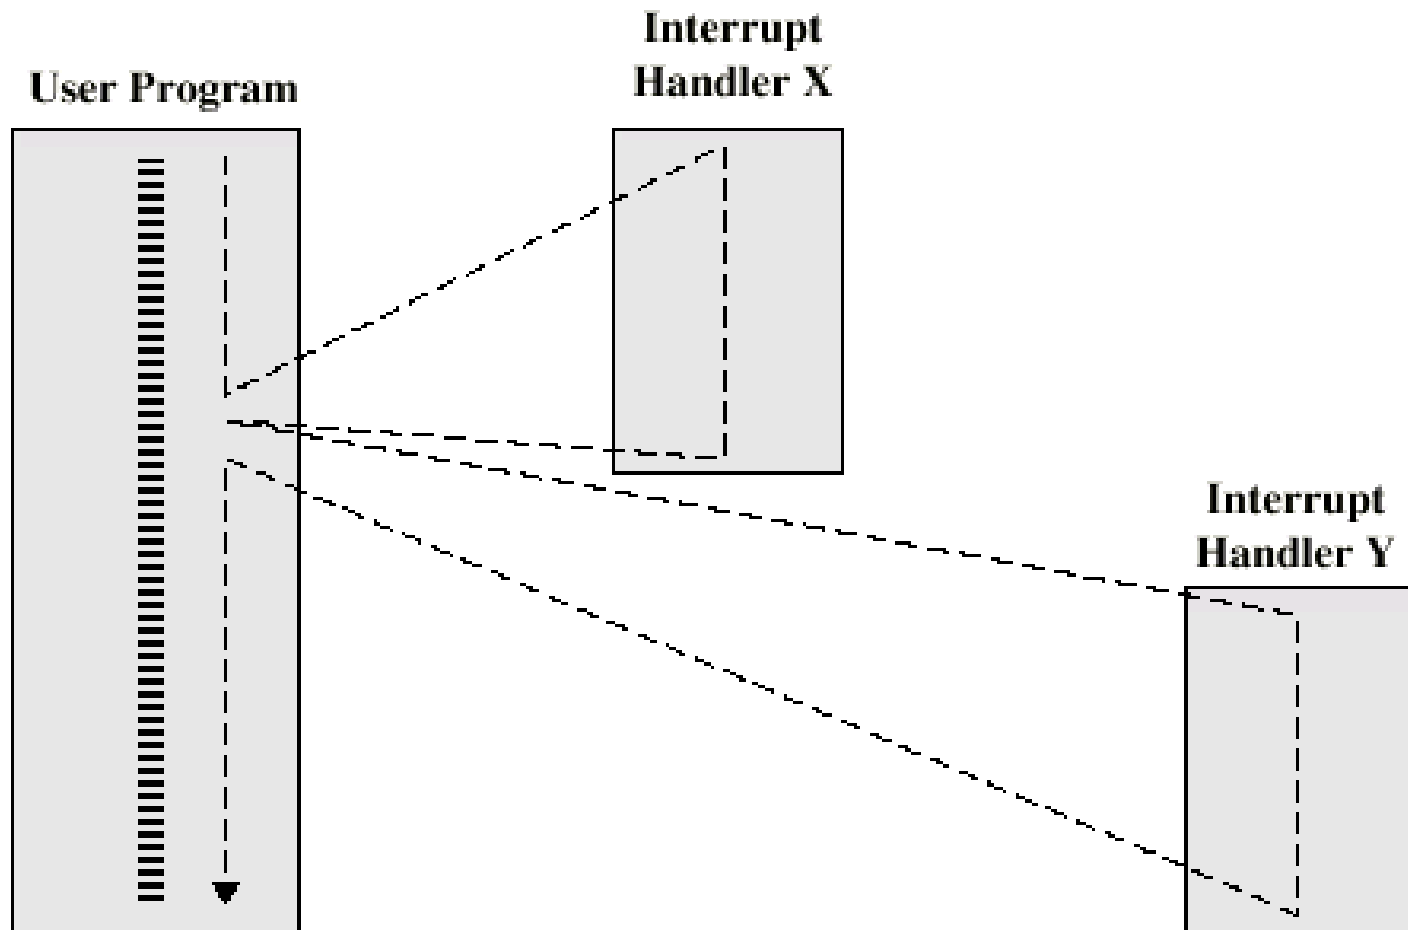

Instruction Cycle (with Interrupts) - State Diagram

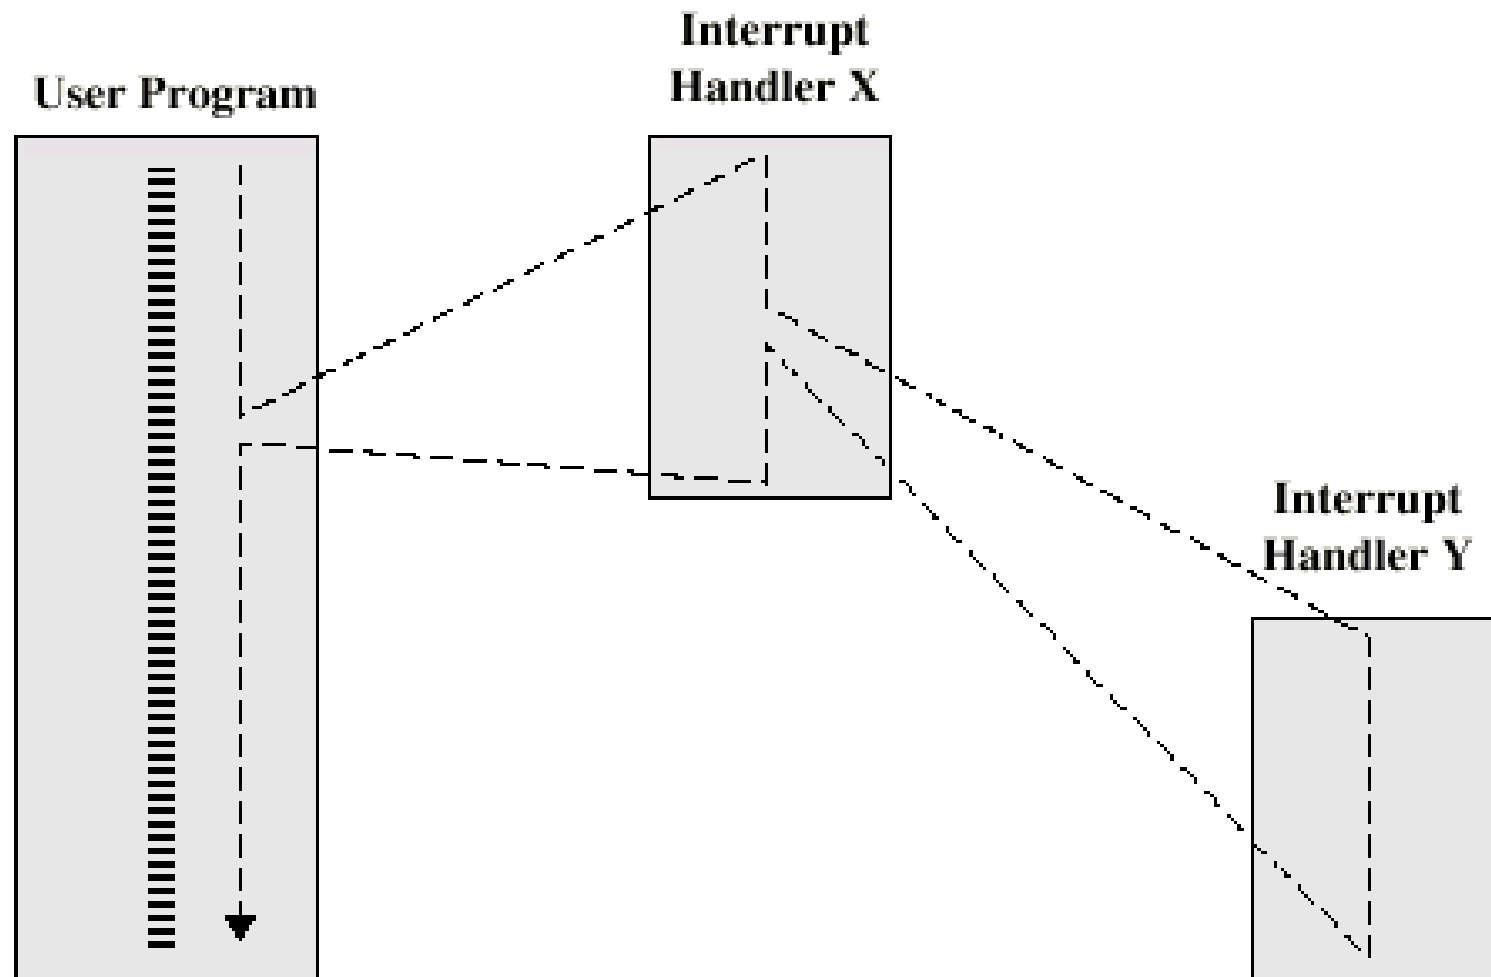

Multiple Interrupts

- Disable interrupts
 - Processor will ignore further interrupts whilst processing one interrupt
 - Interrupts remain pending and are checked after first interrupt has been processed
 - Interrupts handled in sequence as they occur
- Define priorities
 - Low priority interrupts can be interrupted by higher priority interrupts
 - When higher priority interrupt has been processed, processor returns to previous interrupt

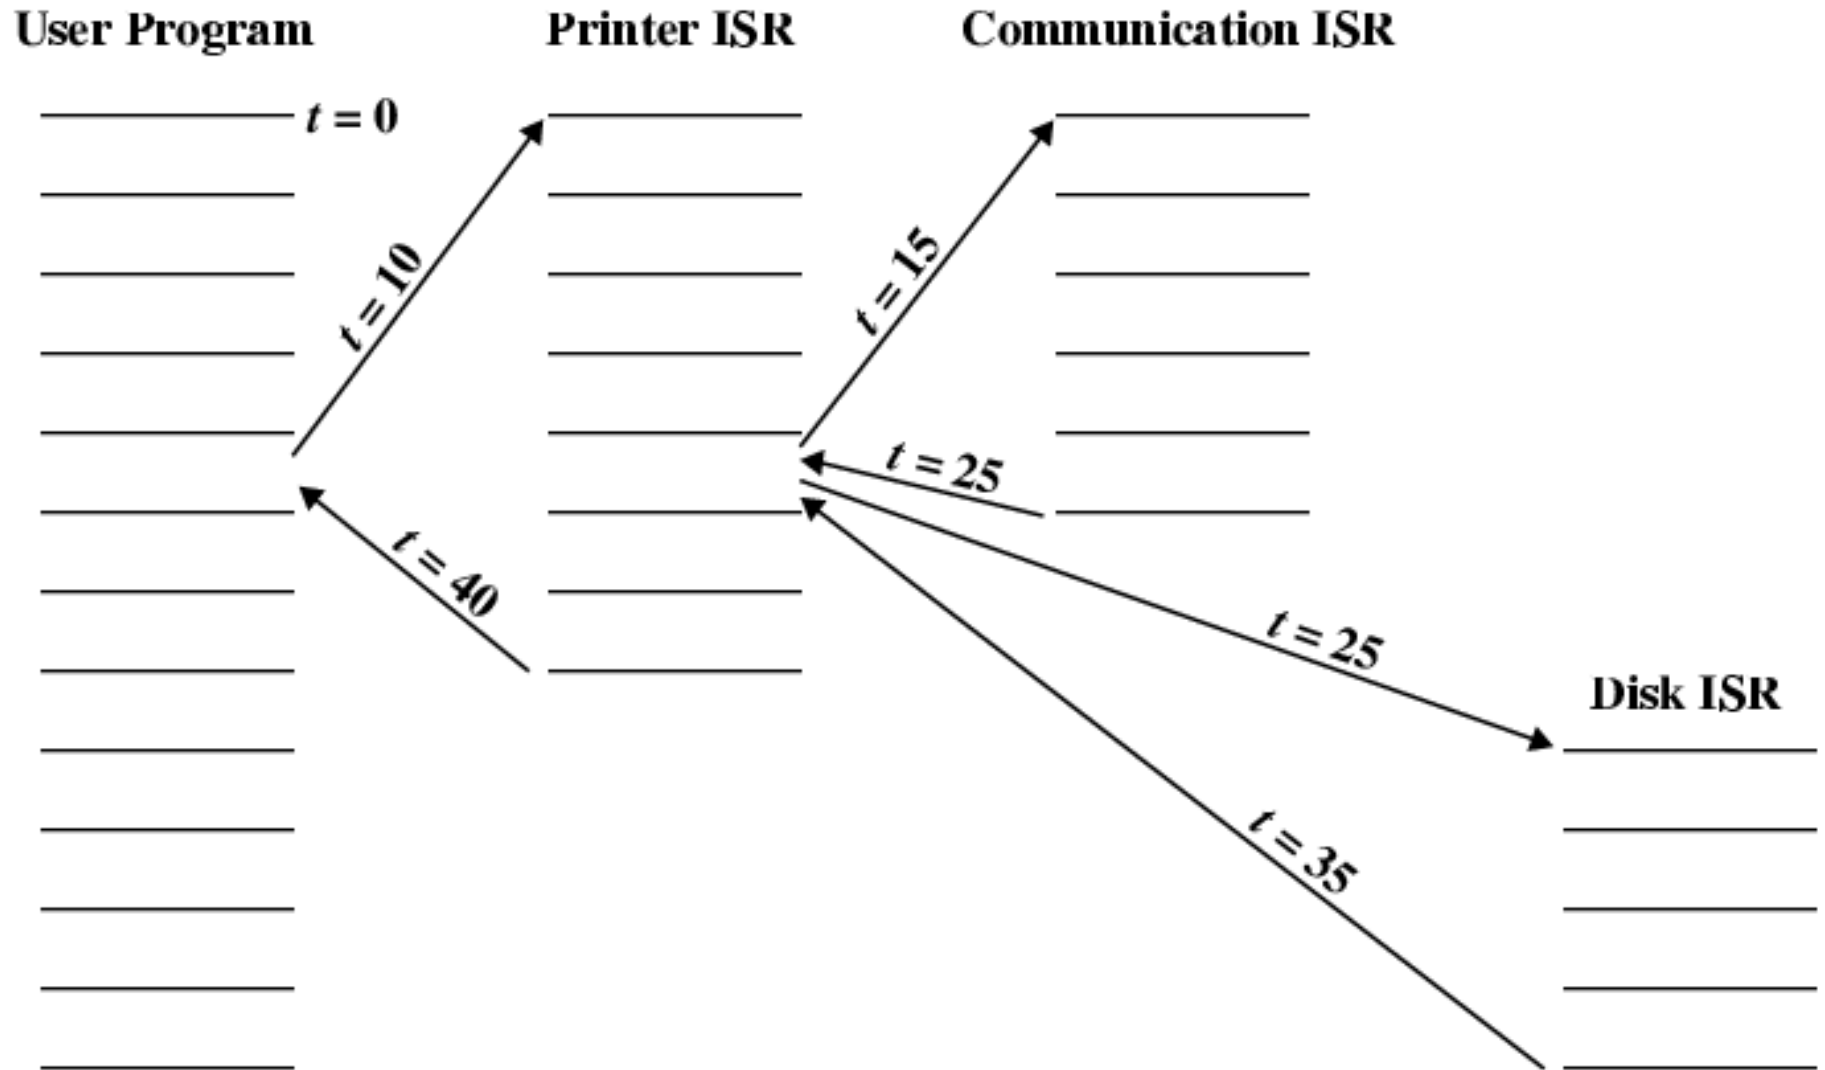

Multiple Interrupts - Sequential

Multiple Interrupts – Nested

Time Sequence of Multiple Interrupts

Connecting

- All the units must be connected
- Different type of connection for different type of unit
 - Memory
 - Input/Output
 - CPU

Computer Modules

Memory Connection

- Receives and sends data
- Receives addresses (of locations)
- Receives control signals
 - Read
 - Write
 - Timing

Input/Output Connection(1)

- Similar to memory from computer's viewpoint
- Output
 - Receive data from computer
 - Send data to peripheral
- Input
 - Receive data from peripheral
 - Send data to computer

Input/Output Connection(2)

- Receive control signals from computer
- Send control signals to peripherals
 - e.g. spin disk
- Receive addresses from computer
 - e.g. port number to identify peripheral
- Send interrupt signals (control)

CPU Connection

- Reads instruction and data
- Writes out data (after processing)
- Sends control signals to other units
- Receives (& acts on) interrupts

The interconnection structure must support the following types of transfers:

**Memory
to
processor**

Processor
reads an
instruction
or a unit of
data from
memory

**Processor
to
memory**

Processor
writes a unit
of data to
memory

**I/O to
processor**

Processor
reads data
from an I/O
device via
an I/O
module

**Processor
to I/O**

Processor
sends data
to the I/O
device

**I/O to or
from
memory**

An I/O
module is
allowed to
exchange
data directly
with
memory
without
going
through the
processor
using direct
memory
access

A communication pathway connecting two or more devices

- Key characteristic is that it is a shared transmission medium

Signals transmitted by any one device are available for reception by all other devices attached to the bus

- If two devices transmit during the same time period their signals will overlap and become garbled

Typically consists of multiple communication lines

- Each line is capable of transmitting signals representing binary 1 and binary 0

Computer systems contain a number of different buses that provide pathways between components at various levels of the computer system hierarchy

System bus

- A bus that connects major computer components (processor, memory, I/O)

The most common computer interconnection structures are based on the use of one or more system buses

Internet Bus connection

Data Bus

- Data lines that provide a path for moving data among system modules
- May consist of 32, 64, 128, or more separate lines
- The number of lines is referred to as the *width* of the data bus
- The number of lines determines how many bits can be transferred at a time
- The width of the data bus is a key factor in determining overall system performance

Address Bus

- Used to designate the source or destination of the data on the data bus
 - If the processor wishes to read a word of data from memory it puts the address of the desired word on the address lines
- Width determines the maximum possible memory capacity of the system
- Also used to address I/O ports
 - The higher order bits are used to select a particular module on the bus and the lower order bits select a memory location or I/O port within the module

Control Bus

- Used to control the access and the use of the data and address lines
- Because the data and address lines are shared by all components there must be a means of controlling their use
- Control signals transmit both command and timing information among system modules
- Timing signals indicate the validity of data and address information
- Command signals specify operations to be performed

Elements of Bus Design

Type		Bus Width	
Dedicated		Address	
Multiplexed		Data	
Method of Arbitration		Data Transfer Type	
Centralized		Read	
Distributed		Write	
Timing		Read-modify-write	
Synchronous		Read-after-write	
Asynchronous		Block	

Bus Interconnection Scheme

Typical Control Signals:

- Memory Write
- Memory Read
- I/O write
- I/O read
- Transfer ACK
- Bus Request
- Bus Grant
- Interrupt Request
- Interrupt ACK
- Clock
- Reset

Big and Yellow?

- What do buses look like?
 - Parallel lines on circuit boards
 - Ribbon cables
 - Strip connectors on mother boards
 - e.g. PCI
 - Sets of wires

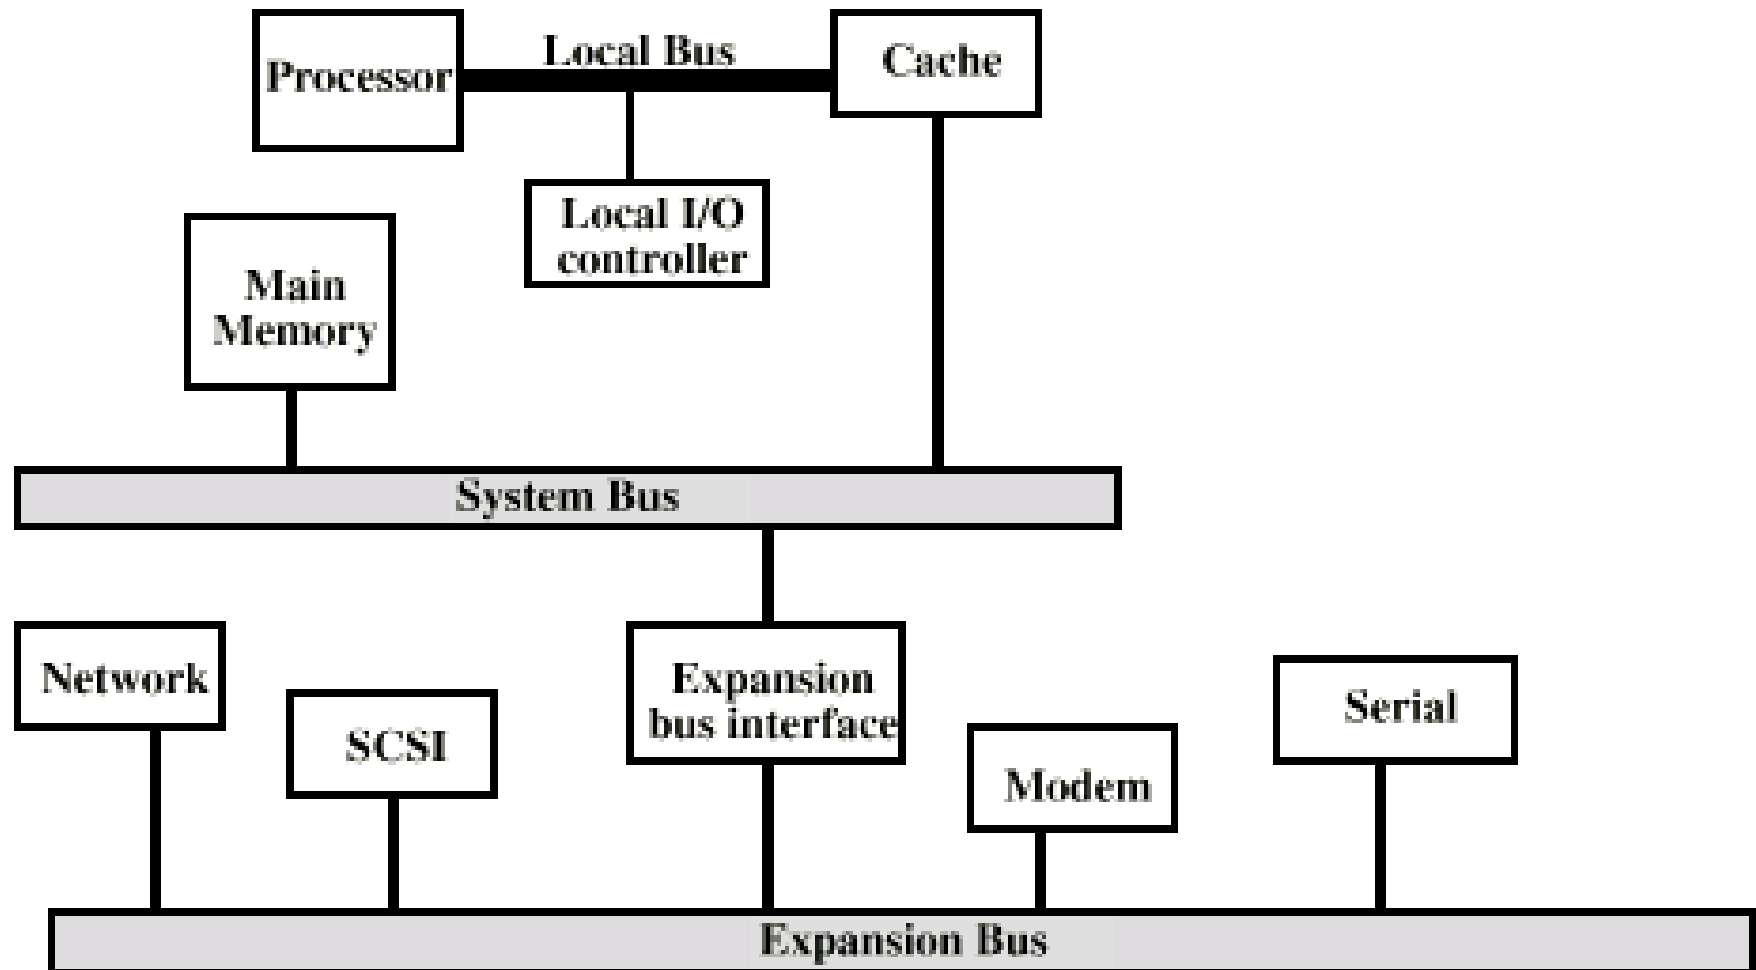

Physical Realization of Bus Architecture

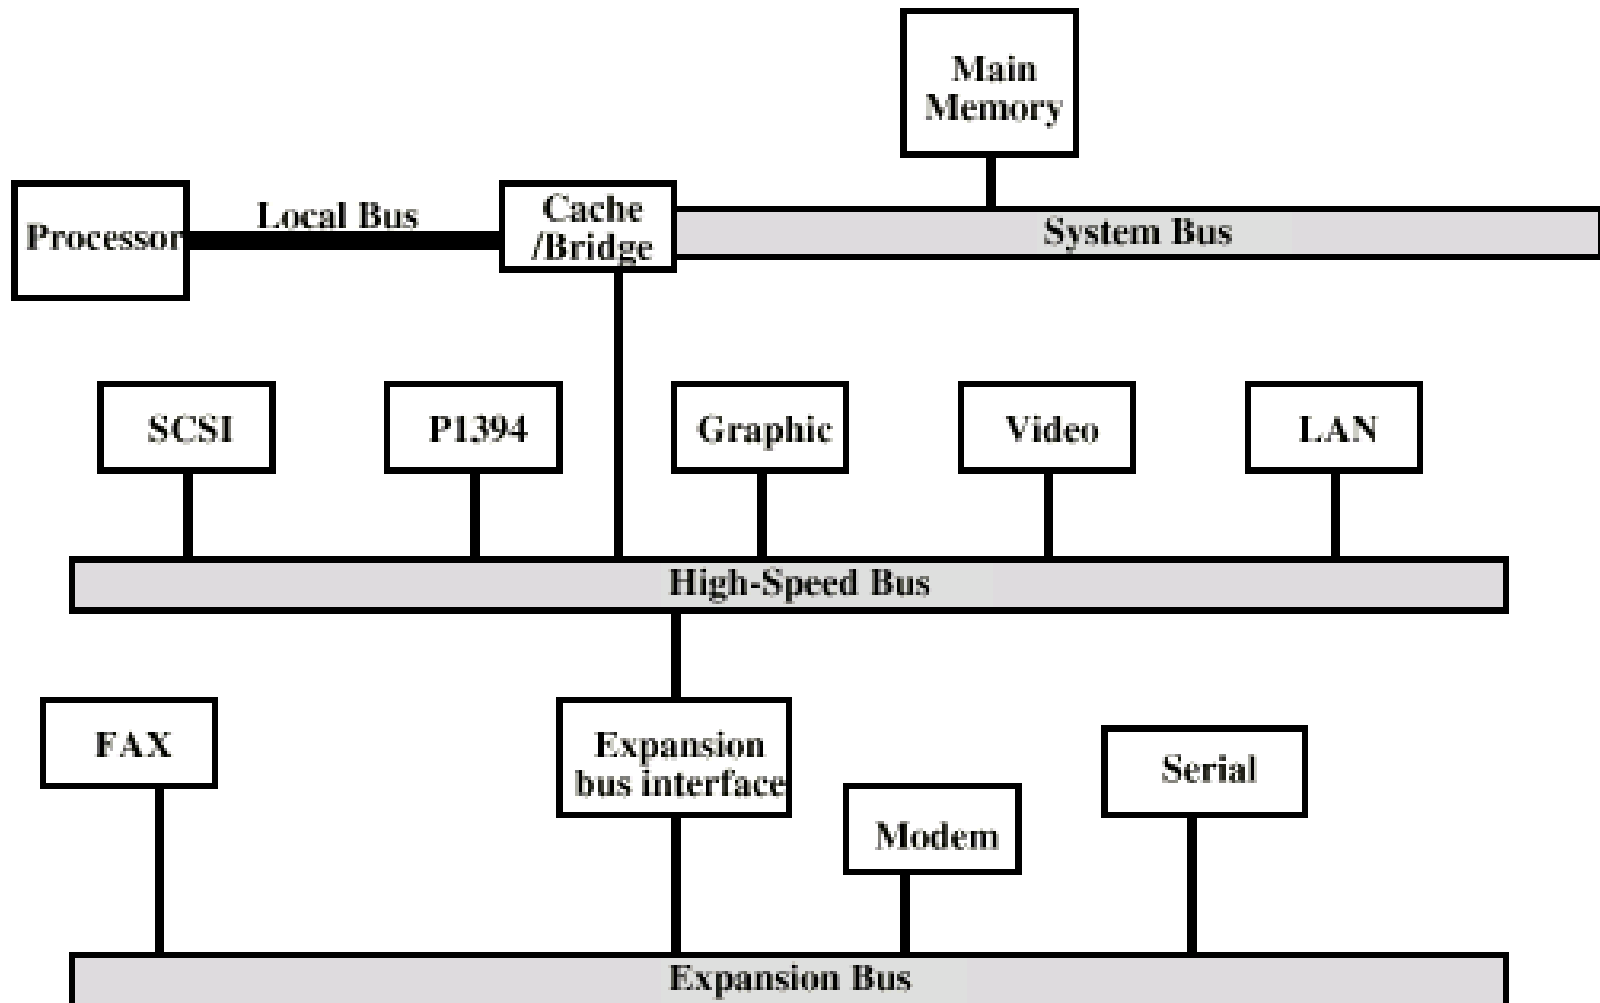

Single Bus Problems

- Lots of devices on one bus leads to:
 - Propagation delays
 - Long data paths mean that co-ordination of bus use can adversely affect performance
 - If aggregate data transfer approaches bus capacity
- Most systems use multiple buses to overcome these problems

Traditional (ISA) (with cache)

High Performance Bus

Bus Types

- Dedicated
 - Separate data & address lines
- Multiplexed
 - Shared lines
 - Address valid or data valid control line
 - Advantage - fewer lines
 - Disadvantages
 - More complex control
 - Ultimate performance

Bus Arbitration

- More than one module controlling the bus
- e.g. CPU and DMA controller
- Only one module may control bus at one time
- Arbitration may be centralised or distributed

Centralised or Distributed Arbitration

- Centralised
 - Single hardware device controlling bus access
 - Bus Controller
 - Arbiter
 - May be part of CPU or separate
- Distributed
 - Each module may claim the bus
 - Control logic on all modules

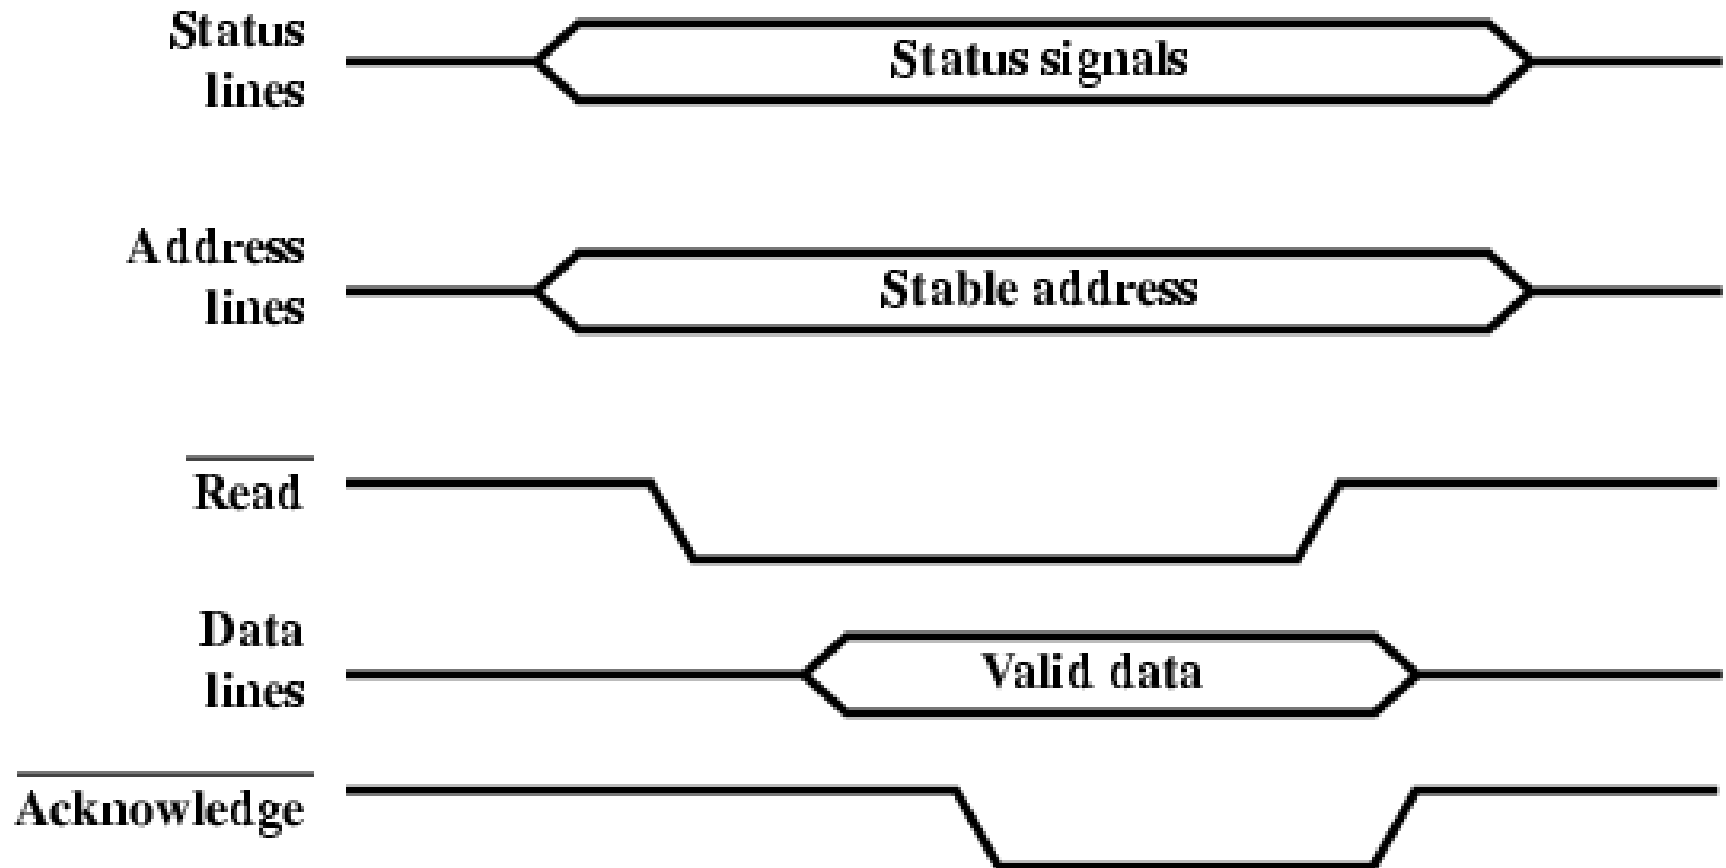

Timing

- Co-ordination of events on bus
- Synchronous
 - Events determined by clock signals
 - Control Bus includes clock line
 - A single 1-0 is a bus cycle
 - All devices can read clock line
 - Usually sync on leading edge
 - Usually a single cycle for an event

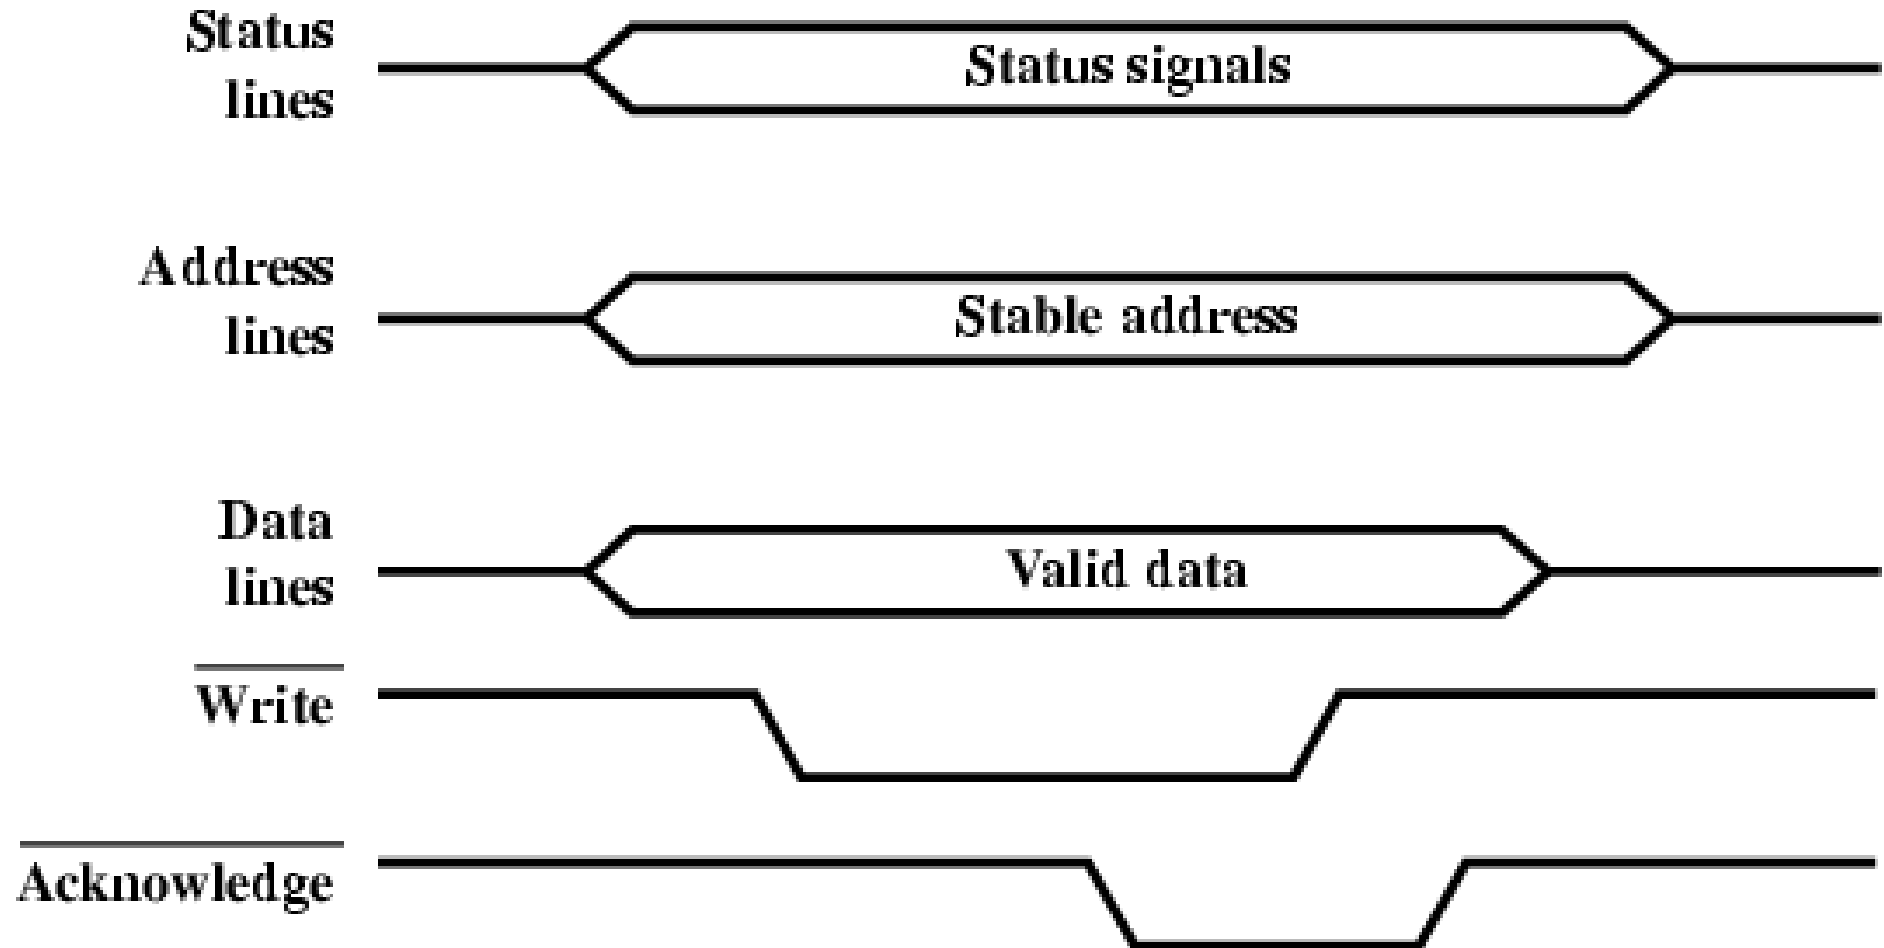

Synchronous Timing Diagram

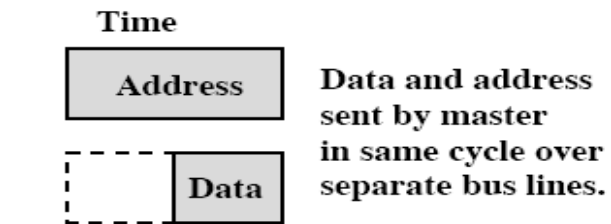

Asynchronous Timing – Read Diagram

Asynchronous Timing – Write Diagram

Write (non-multiplexed) operation

Read (non-multiplexed) operation

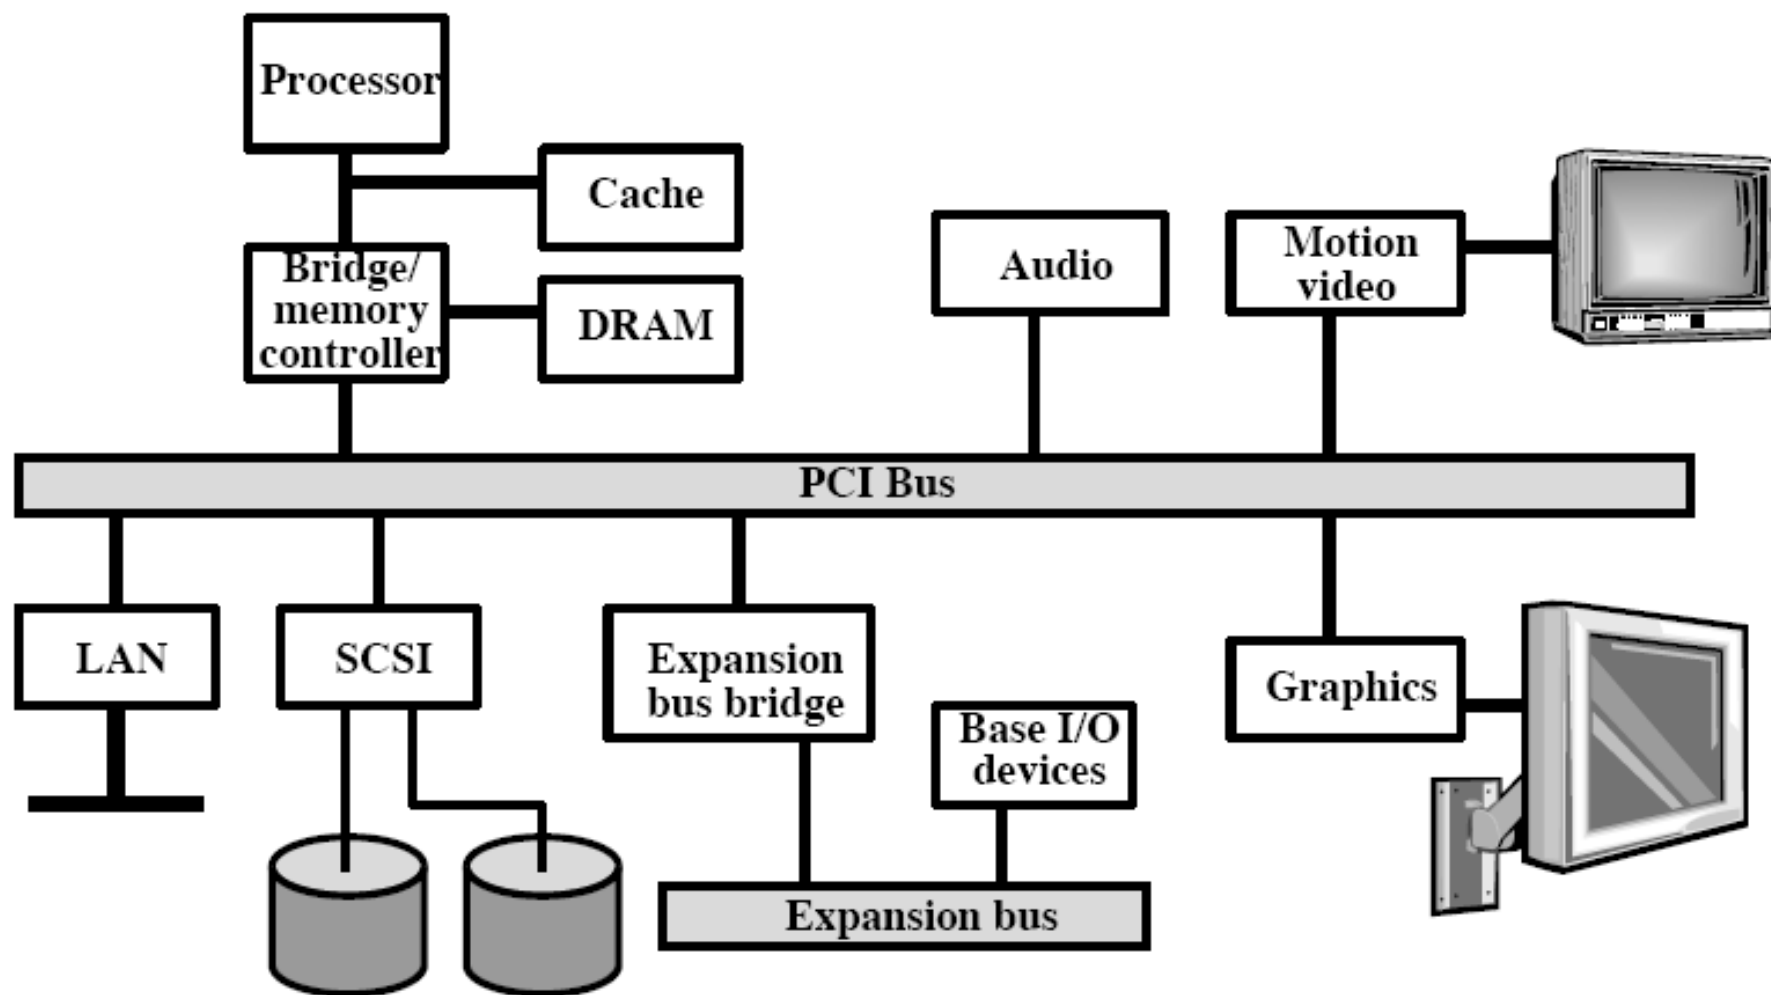

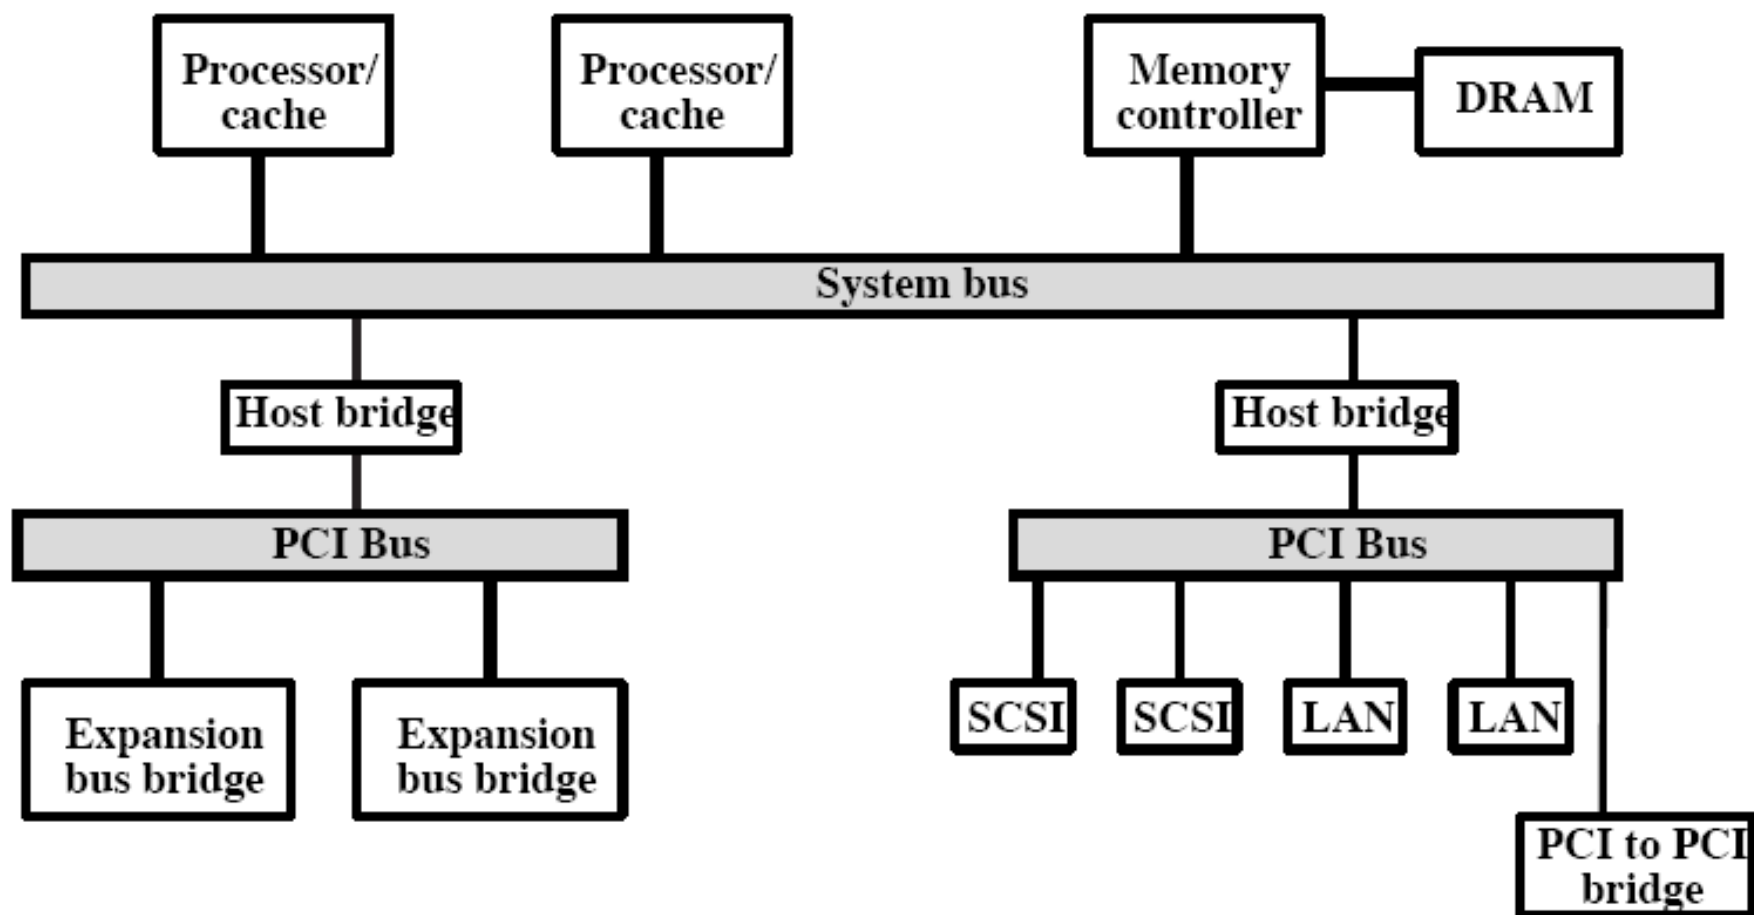

Figure 3.21 Bus Data Transfer Types

(a) Typical desktop system

(b) Typical server system

PCI Bus

- Peripheral Component Interconnection
- Intel released to public domain
- 32 or 64 bit
- 50 lines
- 66MHz for a raw transfer rate of 528MBytes/s or 4.224 Gbps.

PCI Bus Lines (required)

- Systems lines
 - Including clock and reset
- Address & Data
 - 32 time mux lines for address/data
 - Interrupt & validate lines
- Interface Control
- Arbitration
 - Not shared
 - Direct connection to PCI bus arbiter
- Error lines

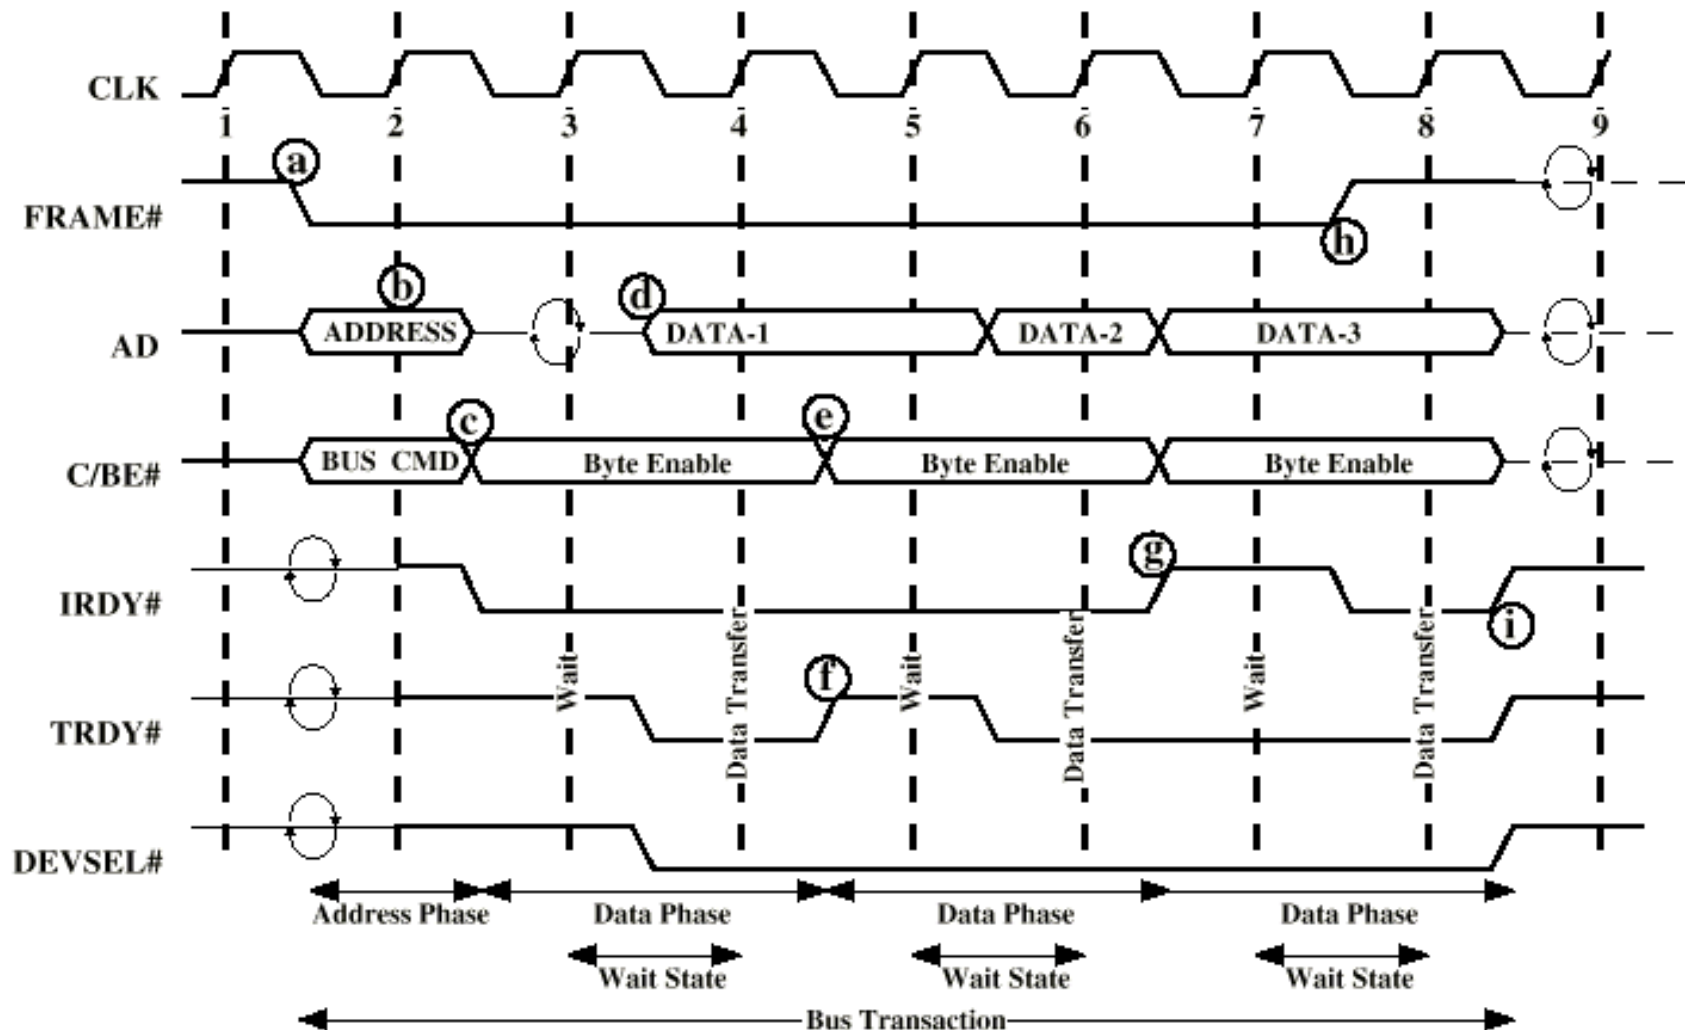

PCI Bus Lines (Optional)

- Interrupt lines
 - Not shared
- Cache support
- 64-bit Bus Extension
 - Additional 32 lines
 - Time multiplexed
 - 2 lines to enable devices to agree to use 64-bit transfer
- JTAG/Boundary Scan
 - For testing procedures

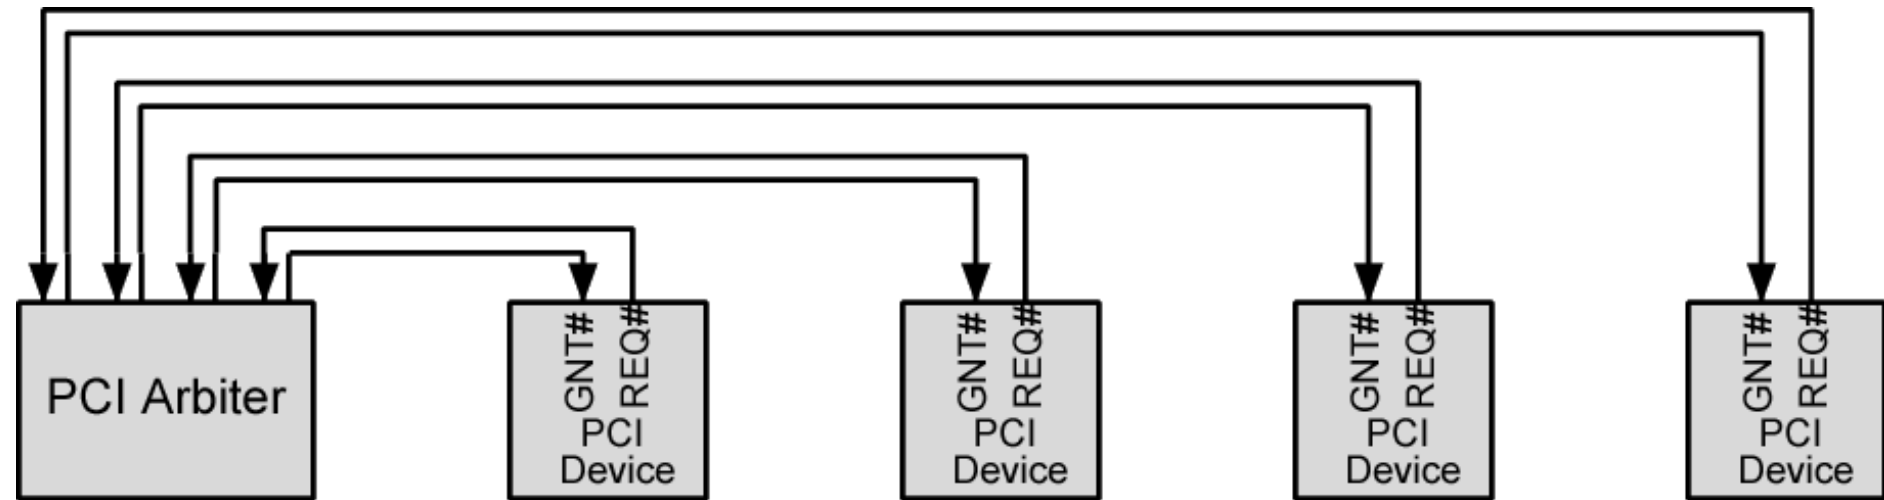

PCI Commands

- Transaction between initiator (master) and target
- Master claims bus
- Determine type of transaction
 - e.g. I/O read/write
- Address phase
- One or more data phases

PCI Read Timing Diagram

PCI Bus Arbiter

PCI Bus Arbitration
